When using multi-thread, care must be taken with application processing.

1. Example of a system construct where the application uses multi-threading, but throughput didn't increase (Printing 4 sheets)

In this example, image and send processes are split by multi-thread. Image processing has higher priority, but until image processing is complete, transmission doesn't begin. Therefore, the time between process start and print processing is longer, and throughput doesn't increase.

2. Countering the above situation

- Use the WindowsXP operating system, and enable HyperThreading.
- Decrease the image processing section priority.

With these measures, image and transmission are distributed for processing, and throughput is increased.
